NASA'S CHANDRA X-RAY OBSERVATORY
On the Front: The galaxy cluster Hydra A is 840 million light years from Earth. The optical image on the right shows many individual galaxies radiating in the visible wavelength. The false color Chandra image on the left, made with the Advanced CCD Imaging Spectrometer (ACIS), shows X-ray emissions. The colors represent the brightness of the X-rays, with white being the brightest. The Chandra image shows the complex inner structure of the large cloud of multimillion degree gas. Long strands of 35 million degree gas are seen expanding away from the center of the cluster. They may be deflected by magnetic fields produced by explosions from the vicinity of a supermassive black hole at the core of the central galaxy. As the largest gravitationally bound objects in the Universe, galaxy clusters provide crucial clues for understanding the origin and fate of the Universe.

What is the X-ray Universe?
The light produced by stars and clouds of gas in space comes in many forms, from low energy radio waves, through infrared and optical radiation, to high energy X-rays and gamma rays. The “X-ray Universe” refers to the Universe as observed with telescopes designed to detect X-rays. We could equally well speak of “the radio Universe” or “the optical Universe.” These are not separate Universes. They are just different ways of observing the same Universe.

Why observe the Universe with different types of telescopes?
Because many things cannot be seen by even the most powerful optical telescopes. Radio and infrared telescopes observe cool clouds of gas and dust that are a hundred or more degrees below zero. X-ray telescopes observe extremely hot matter with temperatures of millions of degrees. Without different types of telescopes, we would miss many very important discoveries about the Universe.

Does an X-ray telescope take X-rays of the Universe?
No. The X-ray machine in a doctor’s or dentist’s office is a source of X-rays. An X-ray telescope is not a source of X-rays. The telescope collects and focuses Xradiation from cosmic X-ray sources onto X-ray detectors. The data from these detectors are then used to make an image of the cosmic X-ray source.

From the illustration on the right, determine the relationship between the wavelength of radiation from an object and its temperature.

What kind of radiation do humans give off?
For clues, check out the X-ray Astronomy section of our web site at http://chandra.harvard.edu
